

Modeling PaEON biomass

Wesley Brooks

UW-Madison

May 24, 2013

Outline

1 Data

- Overview of the data
- Models

2 Methodological details

- Branching process details

Goal

- Produce a model of per-species biomass at time of settlement

Table of Contents

1 Data

- Overview of the data
- Models

2 Methodological details

- Branching process details

Data

- Computed from settlement-era survey
- Working with composition, biomass, and stem density

2 Methodological details

- Branching process details

Models

There are two divisions for modeling biomass data:

		Estimation method		
		<i>Splines</i>	<i>GMRF</i>	<i>GLM</i>
Model	One-stage	Zero-inflated gamma		
		Tweedie		
	Two-stage	Bernoulli-Gamma		

Two-stage models

- First stage: zero/non-zero
 - ▶ Logistic regression
 - ▶ $Z \sim \text{Bernoulli}(\gamma)$
 - ▶ $\text{logit}(\gamma) = f(x, y, p_k)$
- Second stage: distribution of positive biomass
 - ▶ $Y|Z = 1 \sim \text{Gamma}(\alpha, \beta)$
 - ▶ $E(Y|Z = 1) = \mu = \alpha\beta = f(x, y, p_k)$

Tweedie model

The Tweedie model is a Gamma-Poisson mixture.

How to visualize a Tweedie random variable:

- Draw $N \sim \text{Poisson}(\lambda)$
- Now make N iid draws: $V_\ell \sim \text{Gamma}(\alpha, \beta)$
- $Y = \sum_{\ell=1}^N V_\ell$

GLMs, Independent observations

Splines
